

# MSTR & ASST by the Numbers

EVERGREEN EDITION • OCT 2026

The treasury-stock math toolkit. Seven checks to run on any bitcoin treasury stock before you buy, with Strategy first and Strive second.

**How to use this.** Every formula works with any bitcoin treasury company. Plug in today's figures from the company's own filings and dashboard, then write the as-of date next to each one. All worked examples use one made-up company, **Example Co.**, with round **example numbers, not real data**. For live calculators, see the **Treasury Math Lab** at [btctreasurydesk.com/lab/](https://btctreasurydesk.com/lab/).

## 1 mNAV: what you pay vs. the bitcoin

STRATEGY'S KPI

"mNAV represents a multiple of Bitcoin NAV, as of the specified date, calculated as the Company's enterprise value (as we define it) divided by Bitcoin NAV."

Strategy, 8-K Ex. 99.2, filed Dec 1, 2025 • [SEC ↗](#)

Bitcoin NAV "means the market value of our bitcoin holdings calculated by multiplying the current market price of one bitcoin by the total number of bitcoins that we hold."

Strategy, Q3 2025 results release, filed Oct 30, 2025 • [SEC ↗](#)

In that Dec 1, 2025 filing, Strategy's enterprise value is **(A)** the market value of all MSTR common shares, plus **(B)** debt principal, plus **(C)** the notional value of its perpetual preferred stock, minus **(D)** its most recently reported cash.

**Bitcoin NAV = BTC held × BTC price**

**Enterprise value = market cap + debt + preferred - cash**

**mNAV (Strategy) = enterprise value ÷ Bitcoin NAV**

**Simple mNAV = market cap ÷ Bitcoin NAV** (the Lab's quick version)

Strategy says neither number is "net asset value" in the traditional sense. Websites mix the two versions, so always check which one you're looking at. To compare Strategy with Strive, run the same formula on both yourself.

### EXAMPLE CO. INPUTS

EXAMPLE • NOT REAL DATA

|                                           |           |
|-------------------------------------------|-----------|
| Diluted shares                            | 1,000,000 |
| Share price                               | \$60      |
| Bitcoin held                              | 500 BTC   |
| Bitcoin price                             | \$100,000 |
| Debt (principal) · 2% interest            | \$10M     |
| Preferred stock (notional) · 10% dividend | \$10M     |
| Cash / USD reserve                        | \$3M      |

### EXAMPLE CO. MNAV

EXAMPLE • NOT REAL DATA

|                                     |              |
|-------------------------------------|--------------|
| Market cap = 1,000,000 × \$60       | \$60M        |
| Bitcoin NAV = 500 × \$100,000       | \$50M        |
| Enterprise value = 60 + 10 + 10 - 3 | \$77M        |
| mNAV (Strategy method) = 77 ÷ 50    | <b>1.54x</b> |
| Simple mNAV = 60 ÷ 50               | <b>1.20x</b> |

## 2 Implied BTC price and premium

OUR MATH

This is the bitcoin price you are effectively paying when you buy the stock instead of the coin. When mNAV is above 1, you are paying a premium. When it is below 1, the stock trades at a discount to its bitcoin.

**Premium (or discount) = mNAV - 1**

**Implied BTC price = market cap ÷ BTC held** (simple)

**Implied BTC price = enterprise value ÷ BTC held** (EV basis)

A premium is not good or bad by itself. The stock has to earn it by growing BTC per share faster than the premium shrinks. Section 4 shows how to estimate how long that takes.

### EXAMPLE CO. PREMIUM

EXAMPLE • NOT REAL DATA

|                                           |                  |
|-------------------------------------------|------------------|
| Simple premium = 1.20 - 1                 | <b>+20%</b>      |
| EV-basis premium = 1.54 - 1               | <b>+54%</b>      |
| Implied BTC price = \$60M ÷ 500           | <b>\$120,000</b> |
| Implied BTC price, EV basis = \$77M ÷ 500 | <b>\$154,000</b> |
| Actual bitcoin price (input)              | \$100,000        |

## 3 BTC per share and sats per share

STRATEGY'S KPI

"Bitcoin Per Share (in Sats) ("BPS (in Sats)") represents the ratio between the Company's gross bitcoin holdings and its Assumed Diluted Shares Outstanding, expressed in terms of "Satoshis" or "Sats"..."

Strategy, 10-Q for the quarter ended Jun 30, 2026 • [SEC ↗](#)

**BTC per share = BTC held ÷ diluted shares**

**Sats per share = BTC per share × 100,000,000**

**BTC NAV per share = BTC per share × BTC price**

**Strive check:** Strive's "Assumed Fully Diluted Shares Outstanding" states that "Shares underlying Traditional Warrants are excluded from this figure" (8-K filed Sep 28, 2026, [SEC ↗](#)). Run the numbers a second time with the warrants added in.

### EXAMPLE CO. PER SHARE

EXAMPLE • NOT REAL DATA

|                                        |                    |
|----------------------------------------|--------------------|
| BTC per share = 500 ÷ 1,000,000        | 0.0005 BTC         |
| Sats per share = 0.0005 × 100M         | <b>50,000 sats</b> |
| BTC NAV per share = 0.0005 × \$100,000 | <b>\$50.00</b>     |
| Share price (input)                    | \$60.00            |

Example Co.'s \$60 share price buys \$50 of bitcoin per share. That 1.20x ratio is the simple mNAV again, worked out per share.

**4 BTC Yield**

STRATEGY'S KPI · ATTRIBUTED

"BTC Yield represents the percentage change in BPS (in Sats) from the beginning of a period to the end of a period."

Strategy, 10-Q for the quarter ended Jun 30, 2026 · [SEC ↗](#)

"BTC Yield is not equivalent to "yield" in the traditional financial context."

Same filing. It is not income and not your return on the stock.

$$\text{BTC Yield} = (\text{ending sats per share} \div \text{starting sats per share}) - 1$$

$$\text{BTC Gain} = \text{BTC held at start} \times \text{BTC Yield}$$

$$\text{Months to cover premium} \approx \text{premium} \div (\text{annual BTC Yield} \div 12)$$

That last line is a simple rule of thumb also used on the Lab page. It assumes both the premium and BTC Yield stay constant, which they rarely do.

EXAMPLE CO. · 1 YEAR

EXAMPLE · NOT REAL DATA

|                                                                     |                  |
|---------------------------------------------------------------------|------------------|
| Sats per share, start of year                                       | 50,000           |
| Sats per share, end of year                                         | 52,000           |
| BTC Yield = $52,000 \div 50,000 - 1$                                | <b>4.0%</b>      |
| BTC Gain = $500 \times 4.0\%$                                       | <b>20 BTC</b>    |
| Months to cover a 20% premium at 4.0%/yr<br>= $20 \div (4 \div 12)$ | <b>60 months</b> |

**5 Dilution check**

OUR MATH

Treasury companies sell new shares to buy bitcoin. More shares is not automatically bad. What matters is whether **bitcoin grew faster than the share count**.

$$\text{Share growth} = \text{new diluted shares} \div \text{old} - 1$$

$$\text{BTC growth} = \text{new BTC held} \div \text{old} - 1$$

$$\text{Accretive if BTC growth} > \text{share growth (sats per share rise)}$$

Ignoring fees, selling common stock to buy bitcoin raises sats per share only when the stock sells above its BTC NAV per share, meaning a simple mNAV above 1. Below 1, the same sale lowers it. Compare the share count in each new filing with the one before it, and include options, convertibles and warrants.

SELL 100K NEW SHARES

EXAMPLE · NOT REAL DATA

|                                                            |                       |
|------------------------------------------------------------|-----------------------|
| At \$60 (1.20x): raises \$6M → 60 BTC                      | 560 BTC               |
| Sats per share = $560 \div 1.1\text{M} \times 100\text{M}$ | <b>50,909 (+1.8%)</b> |
| At \$40 (0.80x): raises \$4M → 40 BTC                      | 540 BTC               |
| Sats per share = $540 \div 1.1\text{M} \times 100\text{M}$ | <b>49,091 (-1.8%)</b> |
| Share growth in both cases                                 | +10%                  |

**6 Debt and preferred dividends**

GENERIC CHECK

Preferred dividends and debt interest are cash the company owes no matter what bitcoin does. Strategy defines "Dividends" for this purpose as "dividends on preferred stock and interest on outstanding indebtedness" and has said, "We will target the reserve at a minimum of 12 months of Dividends" (8-K Ex. 99.2, Dec 1, 2025, [SEC ↗](#)). Targets can change, so check the latest filing.

$$\text{Annual obligations} = \sum (\text{preferred notional} \times \text{dividend rate}) + \sum (\text{debt} \times \text{interest rate})$$

$$\text{Months of coverage} = \text{USD reserve} \div (\text{annual obligations} \div 12)$$

$$\text{Years of coverage} = \text{Bitcoin NAV} \div \text{annual obligations}$$

$$\text{Breakeven} = \text{annual obligations} \div \text{Bitcoin NAV (\% of BTC value per year)}$$

The last two mirror the "Years of Dividend Coverage" and "BTC Breakeven ARR" in that same Dec 1, 2025 deck. Strategy calls them illustrative, not a solvency measure. Variable-rate preferreds (STRC at Strategy, SATA at Strive) can reset, so use the **current** rate. Remember the pecking order too: debt is paid before preferreds, and preferreds before common stock.

EXAMPLE CO. DEBT + PREFS

EXAMPLE · NOT REAL DATA

|                                                       |                      |
|-------------------------------------------------------|----------------------|
| Preferred: $\$10\text{M} \times 10\%$                 | \$1.0M/yr            |
| Debt interest: $\$10\text{M} \times 2\%$              | \$0.2M/yr            |
| Annual obligations                                    | <b>\$1.2M/yr</b>     |
| Per month = $1.2 \div 12$                             | \$100k               |
| Months of coverage = $\$3\text{M} \div \$100\text{k}$ | <b>30 months</b>     |
| Years of coverage = $\$50\text{M} \div \$1.2\text{M}$ | <b>41.7 years</b>    |
| Breakeven = $1.2 \div 50$                             | <b>2.4% per year</b> |

Read the breakeven this way: if bitcoin rises more than 2.4% in a year, the dollar value of Example Co.'s bitcoin grows by more than the \$1.2M it owes that year, all else equal.

## 7 What to check before buying

ANY TREASURY STOCK

- ☐ Write the **as-of date** next to every number. Holdings, share counts and rates change every week.
- ☐ Which **mNAV** is it: the enterprise-value version or the simple market-cap version? Who calculated it?
- ☐ **Implied BTC price** vs. the actual BTC price. How big is the premium or discount?
- ☐ **Sats per share** now vs. last quarter. Is it rising or falling?
- ☐ **Share count** trend, including options, convertibles and (for Strive) warrants.
- ☐ **BTC Yield** as defined by the company, and how long it takes to cover the premium.
- ☐ **Annual dividends + interest**, and how many months the cash or USD reserve covers.
- ☐ **Variable rates** (STRC, SATA): what is the current rate, and can it reset?
- ☐ **Debt maturities** and convertible terms in the latest 10-Q or 10-K.
- ☐ Did the company **sell any bitcoin**? Check the holdings history, not the headlines.
- ☐ **Concentration risk**: the stock can fall faster than bitcoin. Could you hold through a 50%+ drop?
- ☐ Read the **risk factors** in the latest filing, and use primary sources (SEC EDGAR and the company site) over social media.
